Application Security

Certificates

Agenda

- Introduction
- Certificate structure
- Extensions
- Usages
- PKCS
- Encodings & formats
- Revoking certificates
- Check if certificate is trusted
- Certificates on the market
- Qualified signatures
- Certificate Signing Request

Introduction

- Certificate is an electronic document which includes:
 - Public key of the subject
 - Identity description of the subject
 - Digital signature of the **trusted** third party
 - Expiration date
- Main goal
 - Having a document which proves your identity in transactions
 - Something similar to driving licence in real life

Introduction

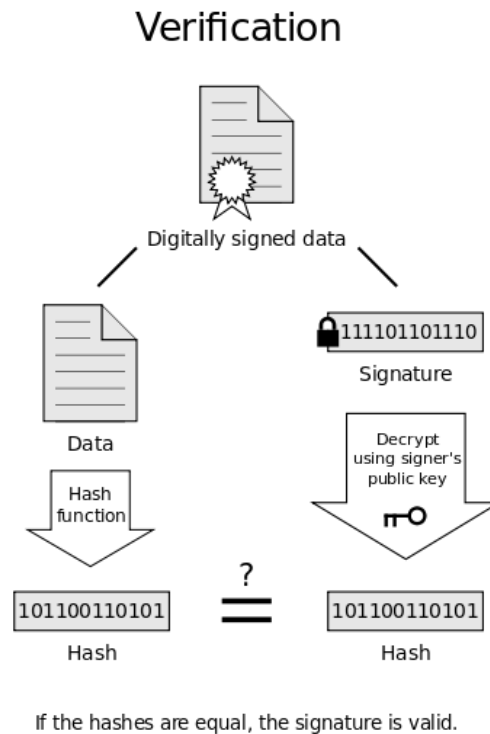

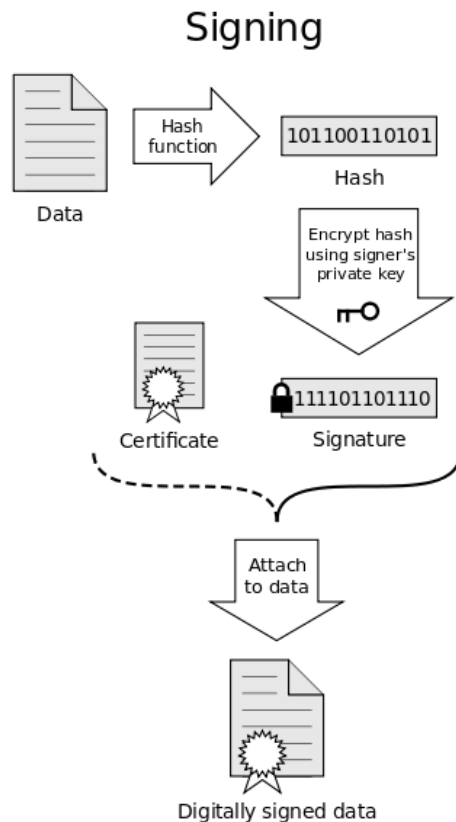

- PKI
 - Stands for Public Key Infrastructure
 - Goal: system for distribution public keys
 - Main constituents
 - Certificates
 - Certificates Authorities (CAs)
 - Method for revoking certificates
 - Method of evaluating chain of certificates
 - General operations
 - Signing: private key to sign, public key to verify signature
 - Encryption: public key to encrypt, private key to decrypt

Introduction

- CA
 - Stands for Certificate Authority
 - A unit which everyone „trust“
 - Every CA has a set of Root CA's
 - <https://www.symantec.com/page.jsp?id=roots>
 - <https://www.symantec.com/content/en/us/about/media/repository/root-certificates.pdf>
 - We consider
 - Root CA – self-signed certificates
 - Intermediate CA – certificate signed by another CA

Introduction

- Digital signature – quick recap

Introduction

- Certificates systems
 - PGP, SPKI/SDSI
 - decentralized, based on WOT
 - X.509
 - based on hierarchy of certificate authorities
- In this presentation we will focus on X.509

X.509: Introduction

- ITU-T standard which allows to create a hierarchical Public Key Infrastructure (PKI)
- Built on top of X.500 family
 - <http://pl.wikipedia.org/wiki/X.500>
- Currently X.509 usually refers to IETF's PKIX Certificate and CRL Profile of the X.509 v3 certificate standard, as specified in RFC 5280
 - <http://tools.ietf.org/html/rfc5280>
- PKIX - Public Key Infrastructure X.509 Working Group (closed in 2013)

X.509: Structure

- Certificate
 - Version
 - Serial Number
 - Algorithm ID
 - Issuer
 - Validity
 - Not Before
 - Not After
 - Subject
 - Subject Public Key Info
 - Public Key Algorithm
 - Subject Public Key
 - Issuer Unique Identifier (optional)
 - Subject Unique Identifier (optional)
 - Extensions (optional)
 - ...
- Certificate Signature Algorithm
- Certificate Signature

X.509: Extensions

- Give additional information about certificate
- Uniquely identified by OIDs
 - Based on ASN.1 syntax
 - http://en.wikipedia.org/wiki/Abstract_Syntax_Notation_One
 - Registry one can find here:
 - <http://www.alvestrand.no/objectid/>
- Extension may be
 - Critical, then certificate system must reject certificate if it is
 - Not recognized or
 - Cannot be processed
 - Not-critical, then certificate system
 - May ignore extension if it is not recognized and
 - Must process if it is recognized

X.509: Extensions

- Examples
 - Subject Key Identifier (OID: 2.5.29.14)
 - A hash derived from the public key of certificate
 - Authority Key Identifier (OID: 2.5.29.35)
 - A hash based on public key of an issuer cert (SKI)
 - or based on issuer name and serial number
 - CRL Distribution Points (OID: 2.5.29.31)
 - A place when information about revocation can be found
 - Netscape Certificate Type (OID: 2.16.840.1.113730.1.1)
 - Define certificate subject to be SSL client, SSL server or CA
 - Basic Constraints (OID: 2.5.29.19)
 - Determine if subject can act as a CA
 - Key Usage (OID: 2.5.29.15)
 - Determine set of allowed usages
- Full list of extensions is defined in RFC:
 - <http://tools.ietf.org/html/rfc5280#section-4.2.1>

X.509: Usages

- Last 3 examples in previous slide define key usage limitation
- Let's see the definition of Key Usage field:

- ```
KeyUsage ::= BIT STRING {
 digitalSignature (0),
 nonRepudiation (1),
 -- recent editions of X.509 have
 -- renamed this bit to contentCommitment
 keyEncipherment (2),
 dataEncipherment (3),
 keyAgreement (4),
 keyCertSign (5),
 cRLSign (6),
 encipherOnly (7),
 decipherOnly (8) }
```

- Good summary from IBM

- [http://publib.boulder.ibm.com/infocenter/domhelp/v8ro/index.jsp?topic=%2Fcom.ibm.help.domino.admin.doc%2FDOC%2FH\\_KEY\\_USAGE\\_EXTENSIONS\\_FOR\\_INTERNET\\_CERTIFICATES\\_1521\\_OVER.html](http://publib.boulder.ibm.com/infocenter/domhelp/v8ro/index.jsp?topic=%2Fcom.ibm.help.domino.admin.doc%2FDOC%2FH_KEY_USAGE_EXTENSIONS_FOR_INTERNET_CERTIFICATES_1521_OVER.html)

# X.509: Usages

- Each certificate is intended to specific usages
  - E.g. Web servers, e-mails, code signing
- VeriSign introduces classes for types of certs:
  - Class 1 for individuals, intended for email.
  - Class 2 for organizations, for which proof of identity is required.
  - Class 3 for servers and software signing, for which independent verification and checking of identity and authority is done by the issuing certificate authority.
  - Class 4 for online business transactions between companies.
  - Class 5 for private organizations or governmental security.
    - <https://www.symantec.com/page.jsp?id=roots>

However, this is not a part of PKI standard

# PKCS Standards

- A set of public-key cryptography standards
- Published by RSA Security Inc. in early 90s
  - Main goal was to promote cryptography techniques to which they had patents
  - Currently, most of them are in the public domain and taken care of organization like IETF and PKIX
- Let's review shortly standards on the next slides
  - List can be found: <http://en.wikipedia.org/wiki/PKCS>

# PKCS Standards

|                | Version | Name                                                                 | Comments                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|---------|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PKCS #1</b> | 2.1     | RSA Cryptography Standard <sup>[1]</sup>                             | See <a href="#">RFC 3447</a> . Defines the mathematical properties and format of RSA public and private keys ( <a href="#">ASN.1</a> -encoded in clear-text), and the basic algorithms and encoding/padding schemes for performing RSA encryption, decryption, and producing and verifying signatures.                                                                                                                     |
| <b>PKCS #2</b> | -       | <i>Withdrawn</i>                                                     | No longer active as of 2010. Covered RSA encryption of message digests; subsequently merged into PKCS #1.                                                                                                                                                                                                                                                                                                                  |
| <b>PKCS #3</b> | 1.4     | <a href="#">Diffie–Hellman Key Agreement Standard</a> <sup>[2]</sup> | A cryptographic protocol that allows two parties that have no prior knowledge of each other to jointly establish a shared secret key over an insecure communications channel.                                                                                                                                                                                                                                              |
| <b>PKCS #4</b> | -       | <i>Withdrawn</i>                                                     | No longer active as of 2010. Covered RSA key syntax; subsequently merged into PKCS #1.                                                                                                                                                                                                                                                                                                                                     |
| <b>PKCS #5</b> | 2.0     | Password-based Encryption Standard <sup>[3]</sup>                    | See <a href="#">RFC 2898</a> and <a href="#">PBKDF2</a> .                                                                                                                                                                                                                                                                                                                                                                  |
| <b>PKCS #6</b> | 1.5     | Extended-Certificate Syntax Standard <sup>[4]</sup>                  | Defines extensions to the old v1 <a href="#">X.509</a> certificate specification. Obsoleted by v3 of the same.                                                                                                                                                                                                                                                                                                             |
| <b>PKCS #7</b> | 1.5     | Cryptographic Message Syntax Standard <sup>[5]</sup>                 | See <a href="#">RFC 2315</a> . Used to sign and/or encrypt messages under a <a href="#">PKI</a> . Used also for certificate dissemination (for instance as a response to a PKCS#10 message). Formed the basis for <a href="#">S/MIME</a> , which is as of 2010 based on <a href="#">RFC 5652</a> , an updated <a href="#">Cryptographic Message Syntax Standard</a> (CMS). Often used for <a href="#">single sign-on</a> . |
| <b>PKCS #8</b> | 1.2     | Private-Key Information Syntax Standard <sup>[6]</sup>               | See <a href="#">RFC 5208</a> . Used to carry private certificate keypairs (encrypted or unencrypted).                                                                                                                                                                                                                                                                                                                      |

# PKCS Standards

|                 |      |                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|------|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PKCS #9</b>  | 2.0  | Selected Attribute Types <sup>[7]</sup>                              | See <a href="#">RFC 2985</a> . Defines selected attribute types for use in PKCS #6 extended certificates, PKCS #7 digitally signed messages, PKCS #8 private-key information, and PKCS #10 certificate-signing requests.                                                                                                                                                                                                                                                                                                                                            |
| <b>PKCS #10</b> | 1.7  | Certification Request Standard <sup>[8]</sup>                        | See <a href="#">RFC 2986</a> . Format of messages sent to a <a href="#">certification authority</a> to request certification of a public key. See <a href="#">certificate signing request</a> .                                                                                                                                                                                                                                                                                                                                                                     |
| <b>PKCS #11</b> | 2.20 | Cryptographic Token Interface <sup>[9]</sup>                         | Also known as "Cryptoki". An <a href="#">API</a> defining a generic interface to <a href="#">cryptographic tokens</a> (see also <a href="#">Hardware Security Module</a> ). Often used in <a href="#">single sign-on</a> , <a href="#">public-key cryptography</a> and <a href="#">disk encryption</a> <sup>[10]</sup> systems. RSA Security has turned over further development of the PKCS#11 standard to the OASIS PKCS 11 Technical Committee.                                                                                                                  |
| <b>PKCS #12</b> | 1.0  | Personal Information Exchange Syntax Standard <sup>[11]</sup>        | Defines a file format commonly used to store <a href="#">private keys</a> with accompanying <a href="#">public key certificates</a> , protected with a password-based <a href="#">symmetric key</a> . PFX is a predecessor to PKCS #12.<br><br>This container format can contain multiple embedded objects, such as multiple certificates. Usually protected/encrypted with a password. Usable as a format for the <a href="#">Java key store</a> and to establish client authentication certificates in Mozilla Firefox. Usable by <a href="#">Apache Tomcat</a> . |
| <b>PKCS #13</b> | –    | <a href="#">Elliptic Curve Cryptography Standard</a> <sup>[12]</sup> | <i>(Under development as of 2012.)</i> <sup>[13]</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PKCS #14</b> | –    | <a href="#">Pseudo-random Number Generation</a>                      | <i>(Under development as of 2012.)</i> <sup>[13]</sup>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>PKCS #15</b> | 1.1  | Cryptographic Token Information Format Standard <sup>[14]</sup>      | Defines a standard allowing users of <a href="#">cryptographic tokens</a> to identify themselves to applications, independent of the application's Cryptoki implementation (PKCS #11) or other <a href="#">API</a> . RSA has relinquished IC-card-related parts of this standard to ISO/IEC 7816-15. <sup>[15]</sup>                                                                                                                                                                                                                                                |

# Encodings & formats

- PEM
  - Encoded with Base64
  - Doesn't support storing the whole path of certificates
  - Doesn't support storing combination of certificate and private key
  - Extensions: .pem, .crt, .cer, .cert, .key
  - Popular in open source solutions (e.g. Apache uses PEM)
- DER
  - Binary representation
  - Doesn't support storing the whole path of certificates
  - Doesn't support storing combination of certificate and private key
  - Extensions: .cer, .der
- PKCS#7
  - Supports storing whole chain of certificates
  - Doesn't support storing private key
  - Extensions: .p7b, .p7c
- PKCS#12 (previously .pfx was predecessor of PKCS#12)
  - Supports storing whole path of certificates
  - Supports storing private key
  - Extensions: .p12, .pfx

# X.509: Revoking certificates

- Certificate revocation allows to avoid certificates which shouldn't be trusted no longer
- There are 2 options: CRL and OCSP
- CRL
  - A file with a list of revoked certificates
  - Location included as an extension field in certificate
  - Signed by CA's private key
    - Let's see sample list from <https://access.redhat.com/home>
- OCSP (Online Certificate Status Protocol)
  - A service which can answer about the status of certificate
  - More efficient than parsing CRL lists
  - Read more
    - [http://en.wikipedia.org/wiki/Online\\_Certificate\\_Status\\_Protocol](http://en.wikipedia.org/wiki/Online_Certificate_Status_Protocol)
    - <http://www.ietf.org/rfc/rfc2560.txt>
  - On lab you will be asked to play with this more 😊

# Check if certificate trusted

- There 2 parts of certificate validation process
  - Path Discovery
  - Path Validation
    - <http://tools.ietf.org/html/rfc3379>
  - Let's see main points of an algorithm
    - [http://en.wikipedia.org/wiki/Certification\\_path\\_validation\\_algorithm](http://en.wikipedia.org/wiki/Certification_path_validation_algorithm)
- Trust is based on Trusted Store Certificate in the system
- DEMO
  - Let's see the list of trusted certificates in IE
  - Let's see the chain of certificates for
    - <https://www.symantec.com/index.jsp>

# Certificates on the market

- We consider 3 levels of validation
  - DV – Domain Validation
    - Only domain is checked in DNS systems
    - No information about organization is included
    - Available in a few minutes
  - OV – Full Organization Validation
    - Additionally organization is checked on the basis of organization documentation
    - Available in 1-2 days
  - EV – Extended Validation
    - More checks are performed: if company has a bank account, there is a phone call with set of questions, etc.
    - Available in 1-10 days
    - Only this type gives a green bar in a web browser

# Certificates on the market

- What means a guarantee of certificate?
  - If something is wrong with a certificate or CA private key, an issuer is obliged to pay compensation
- There is a possibility to buy a wildcard certificate
  - \*.domain.com
- Who sells certificates
  - VeriSign (Symantec ownership)
  - Thawte, Geotrust (part of VeriSign)
  - Comodo
  - GoDaddy
  - TrustWave
  - Certum (in Poland)

# Qualified signatures

- Qualified signature (podpis kwalifikowany)
  - A digital signature based on qualified certificate
    - Usually, if you buy a qualified signature, you get a package
      - Certificate
      - Device with private key
      - Software intended to make signatures
  - In Poland only National Certification Center is allowed to decide who should be able to issue such certificates
    - But it doesn't issue them on its own
    - Let's see their website: <http://www.nccert.pl/>
  - Read more:  
[http://pl.wikipedia.org/wiki/Podpis\\_kwalifikowany](http://pl.wikipedia.org/wiki/Podpis_kwalifikowany)
    - Let's see a short list of applications there

# Certificate Signing Request

- Applicant generates public/private key pair
  - Private key keeps in secret
- Generates CSR (Certificate Signing Request)
  - A file with information about applicant
  - CSR file is signed by private key of applicant
- CSR file with additional documentation is sent to CA
- If everything is ok, CA sent back a certificate signed with a private key of CA

| Information                           |
|---------------------------------------|
| Distinguished Name (DN)               |
| Business name / Organisation          |
| Department Name / Organisational Unit |
| Town/City                             |
| Province, Region, County or State     |
| Country                               |
| An email address                      |
